

1

# Hybridization of Atomic Orbitals

CHAPTER 9

2

## Single bonds

- ▶ Bonding electrons are in between atoms
- ▶ Bonds form when orbitals overlap

3

## Potential energy vs distance btw atoms

- ▶ When two atoms repel each other, what kind of potential energy is in the system?
- ▶ When two atoms attract each other, what kind of potential energy is in the system?
- ▶ When bonding, do molecules want to have high or low potential energy?

4

## Potential energy vs distance btw atoms

5

6

## Two Types of Bonds

- ▶ Sigma bonds ( $\sigma$ ) from overlap of orbitals- **PURPLE**
- ▶ Pi bond ( $\pi$ ) above and below atoms- **PINK**

## Something we have ignored...

7

- ▶ The Lewis dot diagrams for elements, such as C, N or O do not adequately explain/predict how these atoms actually use their orbitals to form bonds
- ▶ A hybridization model was developed in order to explain the bond length/angles and molecular geometry that molecules were experimentally shown to have

## Why do we need this hybrid model?

8

- ▶ Consider water:

- ▶ Facts: O-H bond lengths are equivalent; lone pairs are equivalent

## Orbitals and Electrons in H<sub>2</sub>O

9

- ▶ Each H atom has a single electron ( $1s^1$ )
- ▶ The O atom has 8 total electrons ( $1s^2 2s^2 2p^4$ ), with orbitals filled as shown in diagram
- ▶ The two lone pairs on O ( $2s^2$  and the  $2e^-$  in the first 2p orbital) are not equivalent (shape, size and energy differences between s and p) so logically they should **not** have the same impact on overall geometry...
- ▶ Experiments show that they actually **are** equivalent
  - ▶ Need a new orbital model that reflects this

## Hybridization Model for O

10

- ▶ The lone pairs are not the same here so we need to modify orbital diagram to better match how O bonds in H<sub>2</sub>O

## Orbital Hybridization

11

## sp<sup>3</sup> Orbital Hybridization

12

- ▶ Hybridizing (mixing) 1 s orbital and 3 p-orbitals results in 4 sp<sup>3</sup> orbitals
  - ▶ All 4 orbitals are equivalent in size, shape and energy
  - ▶ Each orbital is 1/4 "s-like" and 3/4 "p-like" and will look somewhere in between these 2 shapes
  - ▶ Notice the number of orbitals hybridized is indicated by the superscript

### sp<sup>3</sup> Hybridization

13

Hybridize to form four sp<sup>3</sup> hybrid orbitals

Copyright © 2009 Pearson Prentice Hall, Inc.

### Filling the Hybridized Orbitals

14

- ▶ The O in H<sub>2</sub>O has equivalent lone pairs (sp<sup>3</sup>) with this new orbital model
- ▶ Two half-filled sp<sup>3</sup> orbitals that will make sigma bonds by overlapping the 1s<sup>1</sup> orbital

### Final shape of H<sub>2</sub>O sp<sup>3</sup> Hybrid

15

Sigma bond

Copyright © 2009 Pearson Prentice Hall, Inc.

### Another Example of sp<sup>3</sup>: (CH<sub>4</sub>)

16

- ▶ The four sp<sup>3</sup> orbitals from C project to the four corners of a regular tetrahedron to minimize electron repulsion

### sp<sup>3</sup> Orbital Diagrams for C, N and O

17

- ▶ sp<sup>3</sup> orbitals only form sigma bonds and will not have any pi bonds due to lack of unchanged p-orbitals

### Types of Hybrid Orbitals (s and p only)

18

## sp<sup>2</sup> Hybrid Orbitals

19

- ▶ The sp<sup>2</sup> hybrids are made from 1 s-orbital and 2 p-orbitals, leaving one p orbital unhybridized
- ▶ sp<sup>2</sup> orbitals make 3 single (sigma) bonds and the 1 unhybridized p-orbital will make 1 pi bond

## sp<sup>2</sup> Hybridization

20

## Example of sp<sup>2</sup> Hybridization

21

- ▶ Ethylene (ethene) : C<sub>2</sub>H<sub>4</sub>
  - ▶ 3 hybrid sp<sup>2</sup> orbitals = 3 sigma bonds
  - ▶ Leaves one p-orbital perpendicular to sigma bond axis which forms a pi bond (double bond)
  - ▶ 3 electron domains so VSEPR shape is trigonal planar

## Ethylene Molecule (C<sub>2</sub>H<sub>4</sub>) Where are the sp<sup>2</sup> hybrid orbitals?

22

- ▶ Hybrid orbitals overlap end-on with s-orbitals of hydrogen atoms; this results in sigma (σ) bond formation
- ▶ 1 sigma bond between carbon atoms

## Ethylene Molecule (C<sub>2</sub>H<sub>4</sub>) Where are the p orbitals?

23

- ▶ Orbitals shaded in **pink** are unhybridized p-orbitals that lie at right angles to the plane of the hybrids
- ▶ These overlap with each other laterally, which results in the formation of a pi (π) bond.

## Ethylene Molecule (C<sub>2</sub>H<sub>4</sub>) Bonding

24

- ▶ C=C consists of 1 σ bond and 1 π bond
- ▶ C—H consists of 1 σ bond

## sp Hybrid Orbitals

25

- ▶ sp hybrids combine 1 s-orbital and 1 p-orbital, leaving 2 unhybridized p-orbitals

## sp Hybridization

26

- ▶ One s-orbital and one p-orbital combine

## sp Hybridization

27

- ▶ sp hybrids will have 2 electron domains (1 single bond and 1 triple bond)
- ▶ 2 domains are located 180° apart to minimize repulsion
- ▶ Linear VSEPR shape

## sp Hybridization Example

28

- ▶ Ethyne:  $C_2H_2$  has a triple bond using 1  $\sigma$  and 2  $\pi$

## $C_2H_2$

29

- ▶ Start with bond

## $C_2H_2$

30

- ▶ Overlap  $\pi$  bonds
- ▶  $C \equiv C$  is 1  $\sigma$  and 2  $\pi$  bonds

31

► Add  $\sigma$  bonds for H

### Example #1

32

Which atom and hybridization pattern does this picture represent?

- A)  $sp^3$  O
- B)  $sp^2$  N
- C)  $sp$  N
- D)  $sp^3$  C
- E)  $sp$  C

### Example #2

33

Which atom and hybridization pattern does this picture represent?

- A)  $sp^3$  N
- B)  $sp^2$  O
- C)  $sp$  C
- D)  $sp^2$  N
- E)  $sp^3$  C

### Example #3

34

Which atom and hybridization pattern does this picture represent?

- A)  $sp$  C
- B)  $sp^2$  N
- C)  $sp^3$  C
- D)  $sp^3$  O
- E)  $sp^3$  N

### Example #4

35

Indicate the  $sp$  hybrid atom(s) in HCN

### Example #5

36

► Label the  $sp^3$  and  $sp^2$  hybrid atoms in the following molecule

### Example #6

37

- ▶ If the bond angle in  $\text{SeH}_2$  is measured to be  $90^\circ$ , what does this tell you about the hybridization of Se?
